Foreword & Overview

SCHOTT Advanced Optics – Your Partner for Excellence in Optics.

SCHOTT, an international technology group, has been developing and manufacturing glass, specialty materials and components for more than 125 years.

Today, the Advanced Optics unit of SCHOTT offers optical materials, components and filters and has been a trailblazer for various applications. With a product portfolio of over 100 optical glasses, special materials (e.g. active laser glass, IR-Materials, sapphire), ultra-thin glass, high-precision optical components, wafers, and optical filter glasses, Advanced Optics develops customized solutions all over the world for applications in optics, lithography, astronomy, opto-electronics, life sciences, research, and more.

Advanced Optics masters the entire value chain: from customer-specific glass development and its production all the way to high-precision optical product finishing, processing and measurement.

Otto Schott (1851–1935)

For more information on Advanced Optics, visit our website: http://www.schott.com/advanced_optics/english/index.html

Product Portfolio of Advanced Optics:

Advanced Optics offers a broad variety of optical materials, filters and components. Here, you will find a concise overview of our main products and applications:

MATERIALS

Optical Glass

SCHOTT offers a wide range of high-quality optical glasses to meet the needs of a broad variety of optical and industrial applications. The portfolio includes lead and arsenic free N-glasses, glasses suitable for precision molding (low Tg glass) as well as glass types with lead oxide as an essential component for outstanding optical properties. In addition, we also offer special versions e.g. "HTultra" glasses with superior transmission.

Low Tg Optical Glass

These special lead and arsenic-free low Tg glasses are suited for precision molding processes (P-glasses). The glass compositions of these glasses have been developed to have low tendencies to devitrification and show less vehement reactions with mold materials inside the molding temperature range.

Active and Passive Laser Glasses

SCHOTT offers cutting edge silicate and phosphate laser glasses for security, medical (dermatology), and a variety of high energy applications. These glasses are offered as finished components with custom polishing or coating.

Radiation Resistant Glass

SCHOTT offers a variety of radiation resistant glass types covering main parts of the Abbe Diagram. These products are suited for earth orbit based applications with lifetimes of up to 10 years.

Radiation Shielding Glass

Radiation shielding glass has been developed specifically for nuclear technology. Some of our glass types contain lead in order to exploit its high radiation absorption.

Technical Glass

SCHOTT's technical glass is designed to meet specific requirements. High electrical resistance for hermetic sealings, superior durability for corrosive environments and high glass transformation temperature all make it the ideal choice for temperature applications.

IR-Materials*

SCHOTT offers chalcogenide glasses with excellent transmission and low thermal change in refractive index. Polycrystalline ZnS FLIR and CLEAR is produced using a CVD process. It is available in large sizes and custom shapes and formats such as windows, domes, or lens blanks. *IR Materials partly provided by our partner VITRON Spezialwerkstoffe GmbH

ZERODUR®

A zero expansion glass-ceramic for demanding applications in which critical geometry and distance accuracy need to be controlled perfectly under temperature changes, with extraordinary properties:

extremely low thermal expansion coefficient, excellent homogeneity of thermal expansion, good workability, polishability to high accuracy and excellent chemical stability.

FILTERS

Optical Filter Glasses

Optical filter glasses ("color glass") absorb the undesirable light spectrum ("colors") and are thus relatively insensitive to a change in the angle of incidence of light, and typically very durable in mechanical terms, as the filter glass can also be hardened. Optical filters, such as IR-cut filters, for example, only admit the light visible to the human eye and block the infrared light spectrum (IR), in particular. SCHOTT offers more than 55 different filter glasses that enable applications in analytics, photography, medical technology and laser protection.

Interference Filters – Customer-specific filter functions

Interference filters use the wave characteristic of light – interference. Band-pass, long-pass, short-pass, and band block filters can be produced by means of thin optical layers. These thin layers are applied under high vacuum using a vapor deposition process. Decorative and protective coatings are also available. SCHOTT uses different technologies for this, such as reactive vapor depositions, reactive ion plating and magnetron sputtering. Our custom designed interference filters are used for applications in medical technology, for analysis of drinking water and clarified water, for fluorescence microscopy, and more. Post-processed filters – cemented or framed, are also available.

COMPONENTS

Windows & Substrates

SCHOTT is a specialist when it comes to producing plane parallel polished substrates of the highest precision. Substrates with diameters up to 625 mm, surface flatness up to $\lambda/20$, roughness below 8 Angstrom, scratch & digs up to 5-2 can be reached. Coatings are also available.

Lenses

Lenses are essential to any optical system. SCHOTT offers various types of lenses: spherical, cylindrical, aspherical (molded or CNC machined, polished, coated), singlets, doublets, and triplets. Diameters of up to 200 mm, surface flatness of up to $\lambda/10$, scratch & digs up to 10-5, and centering better than 30 arc seconds can be achieved.

Prisms

SCHOTT offers prisms as transparent optical elements with flat polished surfaces that refract, reflect or disperse light. SCHOTT supplies all types of prisms: right angle prisms, porro prisms, roof prisms and more in sizes up to 200 mm, surface flatness up to $\lambda/10$, and scratch & digs up to 10-5. Different customer-specific coatings are also available.

Precision CNC Machined Parts

CNC machined parts are optical components which have been processed to complex forms such as laser gyroscope bodies, lithography plates or light weighted mirrors. Coupled with the use of CAD software, nearly all geometrical forms can be achieved with very high accuracy.

Coatings

SCHOTT applies standard and custom-designed coatings. Different coating technologies are available in-house for a typical wavelength spectrum of between 200 nm and 3000 nm. Our portfolio ranges from anti-reflective coatings, mirrors, dielectric beam splitters, and polarizers to high-end interference filters with sharp edges and strong blocking ranges. All types of materials can be coated, for instance fused silica, optical filter glass, and optical glass.

Sub-Assembly

SCHOTT supplies optical and opto-mechanical mounted parts based on customer requirements: e.g. filter assemblies, head-up displays for aviation, prism assemblies, objective lenses. We assure that requirements such as high precision and quality, solid assembling, vacuum tightness and optical properties (such as transmission and reflection) can be met.

Optical Glass Catalog

In this **catalog**, you will find an overview of our optical glasses and materials that cover the needs of a wide range of applications from consumer products to optical systems at the cutting edge of research.

We address the following categories:

- Lead and arsenic free N-glasses
- Low Tg glass types suited for the precision molding process
- Classical glass types with lead oxide as an essential component for outstanding optical properties
- Radiation resistant glass types
- Optical glasses with enhanced transmission values in the visible spectral range, especially in the blue-violet area: HT & HTultra glasses

While addressing these different categories, SCHOTT distinguishes between **Preferred Materials**, usually kept in stock for immediate delivery, and **Inquiry Glass Types**, which can be ordered, although SCHOTT does not guarantee their availability from stock. Details are listed in the data section of the catalog.

Relevant definitions for the materials listed in this catalog:

The cerium-stabilized **radiation resistant glass** types are used to maintain transmittance in an ionizing radiation environment and also rank among our inquiry glasses.

The optical data of the materials listed in this catalog are meant for use in optical applications and therefore refer to air.

For the use of materials in lithography for which transmittance data below 250 nm is required, we kindly ask that you contact us directly to discuss technical aspects in greater detail. This also applies for **i-line glasses**, which are used for lithography due to their superb transmit-

tance in the near-UV range and in optical homogeneity. Upon request, we would be happy to provide you with the respective data sheets and technical support.

Supply Forms

SCHOTT offers **different supply forms** of the materials available. Detailed information is included in chapter 7.

Quality Management

We manufacture, process and distribute our materials in accordance with our Integrated Management System for Safety and Environmental Protection (IMSU) to prevent environmental pollution and conserve natural resources. In addition, SCHOTT recently implemented parts of the new ISO 12123 "Optics and Photonics – Specification of Raw Optical Glass" which is being taken into account in this updated version of this catalog. References are shown in the descriptions.

Further Product Information

One of SCHOTT's main concerns is providing professional support in addition to supplying current products. Extensive technical mentoring, detailed product information and application support before and after a product is purchased and joint developments to a customized solutions describe our uniqueness. We offer detailed data sheets, databases for use with optical design programs and survey diagrams for all materials listed in this catalog. Electronic versions of technical information or so-called TIEs are also available.

The stamp shown here is placed within this catalog and indicates the availability of a relevant TIE. An overview is shown on page 65 of this catalog. Detailed technical information can be found under: http://www.schott.com/advanced_optics/technical_information

TIE
available

1 Optical Properties

1.1 Refractive Index, Abbe Number, Dispersions, Glass Designations

The most common identifying features for characterizing an optical glass are the refractive index n_d in the middle range of the visible spectrum and the Abbe number $v_d = (n_d - 1)/(n_F - n_C)$ as a measure for dispersion. The difference $n_F - n_C$ is referred to as the principal dispersion.

Optical glass can also be designated by a numerical code, often called the glass code. Here, SCHOTT uses a nine-digit code. The first six digits correspond to the common international glass code. They indicate the optical position of the individual glass. The first three digits reflect the refractive index n_d , the second three digits the Abbe value v_d . The additional three digits show the density of the glass.

Table 1.1: Examples of glass codes

Glass type	n_d	v_d	Density	Glass code
N-SF6	1.80518	25.36	3.37	805254.337 lead and arsenic free glass
SF6	1.80518	25.43	5.18	805254.518 classical lead silicate glass

When specifying optical systems, the values based on the e-line n_e and $v_e = (n_e - 1)/(n_F - n_C)$ are other commonly established quantities.

Preferred optical glasses are grouped as families in the n_d/v_d or n_e/v_e diagram. The glass families are listed in the data section in the order of decreasing Abbe values.

1.2 Tolerances for Refractive Index and Abbe Number

The tolerances for the refractive index and Abbe number are listed in table 1.2. The standard delivery quality for fine annealed glass is step 3 for n_d and step 3 for v_d . We supply material in tighter steps upon demand.

Table 1.2: Tolerances for refractive index and Abbe number (according to ISO 12123)

	n_d	v_d
Step 1	± 0.0002	$\pm 0.2\%$
Step 2	± 0.0003	$\pm 0.3\%$
Step 3	± 0.0005	$\pm 0.5\%$
Step 4	–	$\pm 0.8\%$

All deliveries of fine annealed optical glass and cut blanks are made in lots of single batches (see fig.: 1.1).

The batch may be a single block or several strips. The delivery lots are identified by a delivery lot number.

The delivery lots are formed based on the specified maximum allowed refractive index and Abbe number deviation of single batches from the nominal values in the data sheets (tolerances according table 1.2) and the refractive index variation from batch to batch as specified in table 1.3.

As the batches may have different fine annealing histories, such delivery lots are not suitable for repressing.

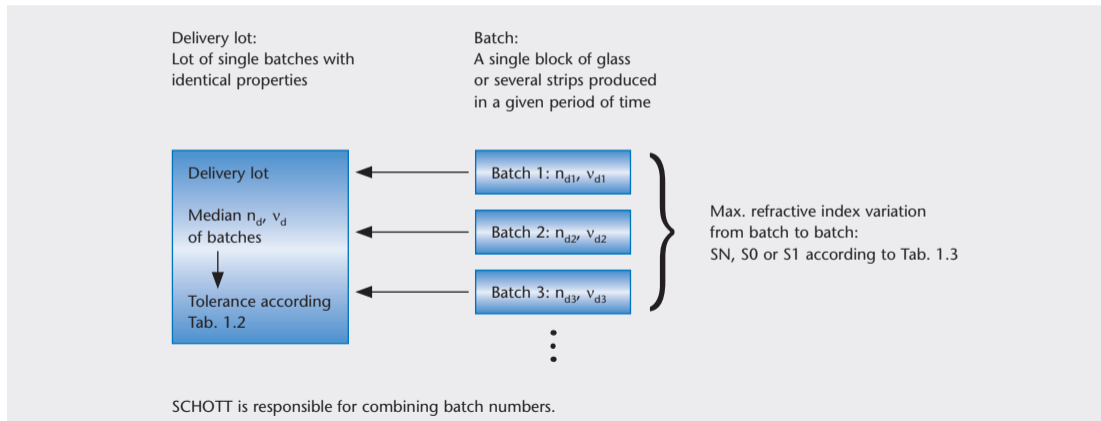

All parts of a delivery lot of fine annealed optical glass, cut blanks or pressings meet the normal quality of refractive index variation as listed in the following table 1.3. If requested, parts can also be supplied in lots with tighter refractive index variations than indicated in table 1.3.

Table 1.3: Tolerance of refractive index variation within a lot of fine annealed glass (according to ISO 12123) and within a lot of pressings

Fine annealed glass, cut blanks		Pressings	
Designation	Refractive index variation	Designation ¹⁾	Refractive index variation
SN	$\pm 1 \cdot 10^{-4}$	LN	$\pm 2 \cdot 10^{-4}$
S0	$\pm 5 \cdot 10^{-5}$	LH1	$\pm 1 \cdot 10^{-4}$
S1	$\pm 2 \cdot 10^{-5}$	LH2	$\pm 5 \cdot 10^{-5}$

¹⁾ All variation tolerances for pressings upon request only

Fig. 1.1: Delivery lot composition of glass for hot processing and fine annealed glass

1.3 Test Reports for Refractive Indices and Dispersions

1.3.1 Standard test reports

We provide standard test reports according to ISO 10474 for all deliveries of fine annealed optical glass. The information they contain is based on sampling tests and refers to the median position of the optical values of a delivery lot. The value of the individual part may deviate from the reported median value by the tolerance of refractive index variation.

Measurements are performed with an accuracy of $\pm 3 \cdot 10^{-5}$ for refractive index and $\pm 2 \cdot 10^{-5}$ for dispersion. Numerical data is listed down to five decimal places.

Table 1.4: Refractive index and dispersion information in standard test reports

n_d	v_d	$n_F - n_C$	$n_F - n_d$	$n_{F'} - n_{C'}$	$n_g - n_F$
n_e	v_e	$n_d - n_C$	$n_F - n_e$	$n_{F'} - n_e$	

Test certificates that are even more accurate can be provided for individual glass parts upon request ($\pm 2 \cdot 10^{-5}$ for refractive index and $\pm 1 \cdot 10^{-5}$ for dispersion). These certificates also list the constants of the Sellmeier dispersion formula for the applicable spectral range evaluated from a complete measurement series.

1.3.2 Precision test certificates UV-VIS-IR

Precision test certificates are issued upon request and always refer to individual glass parts.

Within the visible spectral range, these certificates contain the same quantities as the test reports for standard accuracy, however the dispersion data is reported down to six decimal places. Upon request,

refractive index data can be provided for an expanded spectral range of 185 nm to 2325 nm and the constants of the Sellmeier dispersion formula can be listed for the applicable spectral range.

Measurement is done using a prism goniometer. The accuracy is $\pm 1 \cdot 10^{-5}$ for refractive index and $\pm 3 \cdot 10^{-6}$ for dispersion. Accuracy of up to $\pm 4 \cdot 10^{-6}$ for the refractive index and $\pm 2 \cdot 10^{-6}$ for the dispersion measurement, independent of the glass type and measurement wavelength, can be provided upon request.

The standard measurement temperature is 22°C. The measurement temperature can be changed to a constant value between 18°C and 28°C upon request. The standard measurement atmosphere is air at a pressure of about 1013.3 hPa. The actual

measurement temperature and pressure are indicated on the individual test certificates. Measurement in nitrogen is possible upon special request.

1.4 Refractive Index Homogeneity

The refractive index homogeneity is a measure for designating deviations in the refractive index in individual pieces of glass. Pieces of glass with a high homogeneity of refractive index can be obtained by undertaking special efforts in the area of melting and fine annealing. The refractive index homogeneity that can be achieved depends on the type of glass, the volume and the shape of the individual glass piece.

The required optical homogeneity should be specified with respect to the application and the final dimensions of the part. In general, the optical homogeneity values specified are peak to valley values calculated from measured wave front deviations containing all of the aberrations.

In many cases, you can subtract certain aberration terms of negligible impact on the application. For example, focal aberrations (expressed by the focal term) can often be corrected by adapting the geometry of the final part. This should be specified in advance.

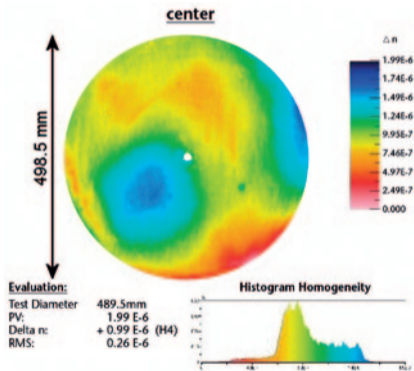

The gradient of homogeneity distribution can be evaluated in terms of refractive index variation per cm aperture upon request. This too should be specified in advance.

Increased requirements for refractive index homogeneity comprise five classes in accordance with the standard ISO 10110 Part 4 (see table 1.5). The maximum variation of refractive index is expressed in peak to valley values in accordance with ISO 12123.

Table 1.5: Homogeneity of optical glasses

Homogeneity class	Maximum variation of refractive index	Applicability, deliverability
H 1	$40 \cdot 10^{-6}$	For individual cut blanks
H 2	$10 \cdot 10^{-6}$	For individual cut blanks
H 3	$4 \cdot 10^{-6}$	For individual cut blanks, not in all dimensions
H 4	$2 \cdot 10^{-6}$	For individual cut blanks, not in all dimensions, not for all glass types
H 5	$1 \cdot 10^{-6}$	For individual cut blanks, not in all dimensions, not for all glass types

Fig. 1.2: H4 quality of a 1 m diameter N-BK7® blank measured with a central aperture of 500 mm

1.5 Internal Transmittance, Color Code

According to general dispersion theory, internal transmittance, i.e. the light transmittance excluding reflection losses, is closely related to the optical position of the glass type. Using the purest raw materials and sophisticated melting technology, it is possible to approach the dispersion limits for internal transmittance in the short wave spectral range.

SCHOTT seeks to achieve the best possible internal transmittance within economically reasonable limits.

The internal transmittance and color code listed in the data section represent median values from several melts of one glass type. Minimum values for internal transmittance can also be maintained for all glass types upon special request. Prior clarification of the delivery situation is necessary. The internal transmittance at 400 nm for a sample thickness of 10 mm is listed in the data section.

Some glasses are available with improved transmittance in the visible spectrum, especially in the blue-violet range. These products are marked with the suffix HT (high transmittance) or HTultra (ultra high transmittance) and will be shown separately in the data section (like N-SF6HT or SF57HTultra). For HT and HTultra grade, the internal transmittance in the visible spectrum includes guaranteed minimum values.

The limit of the transmittance ranges of optical glasses towards the UV area is of particular interest in high index glasses because it moves closer to the visible spectral range with increases in the refractive index. A simple description of the position and slope of the UV absorption curve is shown by the color code.

The color code lists the wavelengths λ_{80} and λ_5 at which the transmittance (including reflection losses) is 0.80 and 0.05 at 10 mm thickness. The values are rounded off to 10 nm and denoted by eliminating the first digit. For example, color code 33/30 means $\lambda_{80} = 330$ nm and $\lambda_5 = 300$ nm.

For high index glass types with $n_d > 1.83$, the data of the color codes (marked by *) refers to the transmittance values 0.70 and 0.05 (λ_{70} and λ_5) because of the high reflection loss of this glass. The tolerance of the color code is usually within ± 10 nm.

1.6 Measurement Capabilities for Optical Properties

Table 1.6 provides an overview of the measurement accuracy for the measurement procedures used to characterize optical properties in quality assurance of optical glass.

	Measurement	Accuracy		Equipment	Spectral Range	Sample	
		refr. index	dispersion			Shape	Format
Refractive index measurement	Standard measurement	$\pm 3 \cdot 10^{-5}$	$\pm 2 \cdot 10^{-5}$	V-block refractometer	g, F', F, e, d, C', C (vd, ve)	cube	20 · 20 · 5 mm ³
	Standard measurement with increased accuracy	$\pm 2 \cdot 10^{-5}$	$\pm 1 \cdot 10^{-5}$		i, h, g, F', F, e, d, C', C, r, t (vd, ve)		
	Precision measurement	$\pm 0.4 \cdot 10^{-5}$	$\pm 0.2 \cdot 10^{-5}$	Spectrometer	185–2325 nm	prism	side: 30 mm height: 22 mm
	Internal transmittance	$\pm 0.5\% T$ $\pm 0.3\% T$		Spectral photometer	250–2500 nm 400–700 nm	cube	30 · 30 · thickness mm ³
	Refractive index homogeneity	~ 10 nm wavefront pv		Interferometer	633 nm	rectangular circular	up to ~ 1000 mm diameter
	Temperature coefficients of refraction	$\pm 5 \cdot 10^{-7} \cdot K^{-1}$		Spectral goniometer	i, h, g, F', e, d, C', t, 1060 -100 °C bis +140 °C	half prism single sided metallized	side: 30 mm height: 22 mm
	High accuracy Stress birefringence	1 nm absolute (1 mm spatial resolution)		Imaging polarimeter	587 nm	arbitrary shape	up to 300 mm diameter

2 Internal Properties

2.1 Striae

Deviations of the refractive index in glass of short range are called striae. They resemble layers in which the refractive index deviates by a typical difference of tenths to several millimeters.

The standard ISO 10110 Part 4 contains a classification with reference to striae. Since it refers to finished optical components, it is only applicable to optical glass in its original form of supply to a limited extent. It assigns the striae to classes 1–4 based on their area in terms of the optically effective total surface of the component. Thus, it only considers striae that deforms a plane wave front by more than 30 nm.

The fifth class specifies glass that is extremely free of striae. It also includes striae below 30 nm wave front distortion and advises the user to make arrangements with the glass manufacturer.

The production formats of all optical glasses from SCHOTT meet the requirements of classes 1–4 of ISO 10110 Part 4. The tested glass thickness is usually much thicker than that of the finished optical components. Therefore, the effective striae quality in the optical system is *much better*.

Striae in all optical glasses are detected by means of the shadowgraph method using comparison standards with known wavefront deviations. The tolerance limits in accordance with ISO 12123 are shown in table 2.1.

Table 2.1: Tolerance limits (according to ISO 12123)

Striae class	Striae wavefront deviation tolerance limit per 50 mm path length [nm]	Generally applicable for
Standard	< 30	raw glass
VS1 / VS2	not visible	cut blanks

Quality step VS1 specifies optical glass with increased striae selection. For optical glass in this quality category, no striae have been detected by the sensitive shadow method. For prism applications, SCHOTT offers quality step VS2. For such glass parts, no striae have been detected by the shadow method in two directions perpendicular to one another.

2.2 Bubbles and Inclusions

Optical glass is remarkably free of bubbles. However, due to the glass composition and the need for an economical manufacturing process, bubbles cannot be completely avoided in glass.

The bubble content is expressed by the total cross section in mm^2 in a glass volume of 100 cm^3 , calculated from the sum of the detected cross section of bubbles. Inclusions in glass, such as stones or crystals, are treated as bubbles that have the same cross section. The evaluation considers all bubbles and inclusions $\geq 0.03 \text{ mm}$.

The bubble classes, maximum allowable quantities and diameters of bubbles and inclusions are listed in table 2.2. In the increased quality steps VB (increased bubble selection) and EVB (extra increased bubble selection), the glasses can only be supplied as fabricated pieces of glass.

In accordance with ISO 10110 Part 3, bubbles may be distributed. Instead of a bubble with a given dimension, a larger quantity of bubbles of smaller dimensions is allowed.

Special applications, such as high energy lasers, beam splitter prisms or streak imaging cameras and high pitch gratings, only tolerate glasses that have a small number of tiny bubbles/inclusions. We can offer glass that meets these requirements upon request.

Table 2.2: Tolerances for bubbles and inclusions in optical glasses

Bubble class		B0	B0	B0	B1	B1	B1
Quality step			VB	EVB		VB	EVB
Maximum allowable cross section of all bubbles and inclusions in mm ² per 100 cm ³ of glass volume		0.03	0.01	0.006	0.1	0.03	0.02
Maximum allowable quantity per 100 cm ³		10	4	2	30	10	4
Maximum allowable diameter of bubbles or inclusions in mm	50	0.10	0.10	0.10	0.15	0.15	0.10
	100	0.15	0.15	0.10	0.20	0.15	0.10
	200	0.20	0.15	0.10	0.30	0.20	0.10
within parts of diameter	300	0.25	0.20	0.10	0.40	0.25	0.10
or max. edge length	500	0.40	–	–	0.60	–	–
in mm	800	0.55	–	–	0.80	–	–

2.3 Stress Birefringence

The size and distribution of permanent inherent stress in glass depends on the annealing conditions, the glass type, and the dimensions. The extent to which stress causes birefringence depends on the glass type.

Stress birefringence is measured as a path difference using the de Sénarmont and Friedel method and is listed in nm/cm based on the test thickness. Its accuracy is 3–5 nm for simple geometric test sample forms. Measurement is performed on round discs at a distance of 5% of the diameter from the edge. For rectangular plates, the measurement is performed at the center of the longer

side at a distance of 5% of the plate width. A detailed description of the method can be found in ISO Standard 11455.

The manual de Sénarmont and Friedel method is insufficient for measurements of low stress birefringence and low thickness. In these cases, we have systems for measuring with an accuracy of 1 nm or less.

With our annealing methods, we are able to achieve both high optical homogeneity and very low stress birefringence. The pieces of glass that are delivered generally have symmetrical stress distribution. The glass surface is usually under compression. Stress birefringence can be reduced significantly by cutting block or strip glass. If the optical elements are much smaller than the raw glass format they are made of, then the remaining stress birefringence will be even much lower than the limiting values shown in table 2.3.

The limit values for stress birefringence in parts larger than 600 mm are available upon request.

Higher stresses are allowed in glass used for reheat pressing. This has no effect on mechanical processing.

Table 2.3: Limit values of stress birefringence in cut blanks for various dimensions (Ø: diameter or maximum length, d: thickness)

Dimensions	Stress birefringence		
	Fine annealing [nm/cm]	Special annealing (SK) [nm/cm]	Precision annealing (SSK) [nm/cm]
Ø ≤ 300 mm d ≤ 60 mm	≤ 10	≤ 6	≤ 4
Ø: > 300–600 mm d: > 60–80 mm	≤ 12	≤ 6	≤ 4

3 Chemical Properties

The five test methods described below are used to assess the chemical durability of polished glass surfaces.

3.1 Climatic Resistance

Climatic resistance describes the behavior of optical glasses at high relative humidity and high temperatures. A film of white stains can develop on the surface of sensitive glasses that generally cannot be wiped off.

An accelerated procedure according to ISO/WD 13384 is used to test the climatic resistance of the glass, in which polished, uncoated glass plates are exposed to water vapor saturated

Table 3.1: Classification of optical glasses into climatic resistance classes CR 1–4

Climatic resistance class CR	1	2	3	4
Increase in haze ΔH	< 0.3%	$\geq 0.3\%$ < 1.0%	$\geq 1.0\%$ < 2.0%	$\geq 2.0\%$

atmosphere, the temperature of which alternates between 40°C and 50°C. This produces a periodic change from moist condensation on the glass surface and subsequent drying.

The glass plates are removed from the climatic chamber after 30 hours of exposure time. The difference ΔH between the haze before and after testing is used as a measure of the resulting surface change. The measurements are performed using a spherical hazemeter. Classification is done based on the increase of transmittance haze ΔH after a 30-hour test period. Table 3.1 lists the climatic resistance classes.

The glasses in class CR 1 show no visible attacks after being exposed to climatic change for 30 hours. Under normal humidity conditions during the fabrication and storing of optical glass in class CR 1, no surface attack can be expected. On the other hand, class CR 4 optical glasses should be manufactured and stored with caution because these glasses are highly sensitive to environmental influences.

When storing optical polished elements, we recommend applying a protective coating and/or ensuring that relative humidity is kept as low as possible.

3.2 Stain Resistance

The test procedure provides information on possible changes in the glass surface (stain formation) under the influence of slightly acidic water (for example perspiration, acidic condensation) without vaporization.

The stain resistance class is determined using the following procedure: The plane polished glass sample to be tested is pressed onto a test cuvette, which has a spherical depression of max. 0.25 mm depth that contains a few drops of a test solution.

Test solution I: sodium acetate buffer pH = 4.6

Test solution II: sodium acetate buffer pH = 5.6

Interference color stains develop as a result of decomposition of the surface of the glass by the test solution. The measure for classifying the glass is the time that elapses before the first brown-blue stain occurs at a temperature of 25 °C. Changes in color correspond to certain thicknesses of the surface layer that were previously determined on reference samples. A brown-blue change in color indicates a chemical change in the surface layer of 0.1 μm thickness insofar as the glass is able to form layers. Table 3.2 lists the stain resistance classes.

Stain resistance class FR 0 contains all glasses that show virtually no interference colors, even after 100 hours of exposure to test solution I. Glasses in classification FR 5 must be handled with particular care during processing.

Table 3.2: Classification of optical glasses into stain resistance classes FR 0–5

Stain resistance class FR	0	1	2	3	4	5
Test solution	I	I	I	I	II	I/II
Time (h)	100	100	6	1	1	0.2
Stain development	no	yes	yes	yes	yes	yes
Color change	no	yes/no	yes	yes	yes	yes

3.3 Acid Resistance

Acid resistance describes the behavior of optical glass that comes in contact with larger quantities of acidic solutions (for example: perspiration, laminating substances, carbonated water, etc.). Acid resistance is determined according to ISO 8424 (1996).

Acid resistance is denoted by either a two or three digit number. The first or first two digits indicate the acid resistance class SR. The last digit, which is separated by a decimal point, indicates the visible surface changes that occurred as a result of exposure. The last digit is discussed in chapter 3.5.

The time required to dissolve a layer with a thickness of $0.1 \mu\text{m}$ at 25°C serves as a measure of acid resistance. Two aggressive solutions are used to determine acid resistance. A strong acid (nitric acid, $c = 0.5 \text{ mol/l}$, pH 0.3) is used for the more resistant glass types, whereas glasses with lower acid resistance are exposed to a weak acidic solution with a pH value of 4.6 (sodium acetate buffer).

The layer thickness is calculated from the weight loss per surface area and the density of the glass. Table 3.3 lists the acid resistance classes.

Class SR 5 forms the transition point between the more acid resistant glasses in SR 1–4 and the more acid sensitive glasses in SR 51–53. Class SR 5 includes glasses for which the time for removal of a layer thickness of $0.1 \mu\text{m}$ at a pH value of 0.3 is less than 0.1 h and at a pH value of 4.6 is greater than 10 hours.

Table 3.3: Classification of optical glasses into acid resistance classes SR 1–53

Acid resistance class SR	1	2	3	4	5	51	52	53	
pH value	0.3	0.3	0.3	0.3	0.3	4.6	4.6	4.6	
Time (h)	> 100	10–100	1–10	0.1–1	< 0.1	> 10	1–10	0.1–1	< 0.1

3.4 Alkali and Phosphate Resistance

Both test methods are used to classify the resistance of glasses to aqueous alkaline solution in excess and use the same classification scheme.

The alkali resistance indicates the sensitivity of optical glass in contact with warm, alkaline liquids, such as cooling liquids in grinding and polishing processes. Alkali resistance is determined according to ISO 10629 (1996).

Phosphate resistance describes the behavior of optical glass during cleaning with washing solutions (detergents) that contain phosphates. Phosphate resistance is determined according to ISO 9689 (1990).

Both alkali and phosphate resistance are denoted using two digits separated by a decimal point. The first digit lists the alkali resistance class AR or the phosphate resistance class PR, and the decimal indicates the visible surface change that occurs as a result of exposure.

The alkali resistance class AR indicates the time needed to remove a 0.1 μm layer thickness of glass in an alkaline solution (sodium hydroxide, $c = 0.01 \text{ mol/l}$, $\text{pH} = 12$) at 50°C .

The phosphate resistance class PR indicates the time needed to remove a 0.1 μm layer thickness of glass in a solution that contains alkaline phosphate (pentasodium triphosphate $\text{Na}_5\text{P}_3\text{O}_{10}$, $c = 0.01 \text{ mol/l}$, $\text{pH} = 10$) at a temperature of 50°C . The layer thickness is calculated from the weight loss per surface area and the density of the glass. Table 3.4 lists the alkali and phosphate resistance classes.

Table 3.4: Classification of the optical glasses to alkali resistance classes AR 1–4 and phosphate resistance classes PR 1–4

Alkali resistance class AR, Phosphate resistance class PR	1	2	3	4
Time (h)	> 4	1–4	0.25–1	< 0.25

Glasses in class 1 are more resistant to the test solutions than the glasses in class 4. The digit behind the classification identifies the visible surface change that occurs following exposure. The digits are covered in chapter 3.5.

3.5 Identification of Visible Surface Changes

Changes in the surface of the exposed samples are evaluated qualitatively with the naked eye. The definition of the digits behind the classification for acid, alkali, and phosphate resistance is as follows:

- .0 no visible changes
- .1 clear, but irregular surface (wavy, pockmarked, pitted)
- .2 staining and/or interference colors (slight, selective leaching)
- .3 tenacious thin whitish layer (stronger, selective leaching, cloudy/hazy/dullish surface)
- .4 adhere loosely, thick layer, such as insoluble, friable surface deposits (maybe a cracked and/or peelable surface, surface crust, or cracked surface; strong attack)

3.6 Environmental Aspects, Hazardous Substances, RoHS

We manufacture, process and distribute our range of materials in accordance with our Integrated Management System for Safety and Environmental Protection (IMSU) and Environmental, Health and Safety Management System (EHS) to prevent environmental pollution, conserve natural resources and follow the procedure and philosophy of our Quality Management System.

Raw materials are handled, batches are melted and hot forming takes place in accordance with established safety procedures. Sludge from cutting, grinding and polishing is treated according to the waste disposal procedures prescribed by local authorities. Glass parts survive their end of usage life

by far without releasing any of their chemical components. Their disposal is a rare and dispersed event to prevent any critical levels from accumulating.

All optical materials in this catalog comply with the requirements of the European Directive 2002/95/EC (RoHS). The optical materials featured in our catalog do not contain any mercury (Hg), chromium VI (CrVI), cadmium or the flame retardants PBB and PBDE whatsoever. N- and P-glass types comply with the limit value of 0.1 % for lead specified in the directive 2005/618/EC that states the admissible limits for the hazardous substances quoted in RoHS. The classical glass types may contain lead oxide in significant amounts. They are in compliance with RoHS due to the exemption documented in the Commission decision 2011/65/EU. In addition, all materials discussed in this catalog comply with the requirements of the European Regulation 2006/1907/EC (REACH: Registration, Evaluation and Authorization of Chemical Substances).

4 Mechanical Properties

4.1 Knoop Hardness

Knoop Hardness expresses the amount of surface changes in a material after indentation of a test diamond at given pressure and time. The standard ISO 9385 describes the measurement procedure for glasses. In accordance with this standard, the values for Knoop Hardness HK are listed in the data sheets for a test force of 0.9807 N (corresponds to 0.1 kp) and an effective test period of 20 s. The test is performed on polished glass surfaces at room temperature. The data for hardness values are rounded off to 10 HK 0.1/20. Micro hardness is a function of the magnitude of the test force and decreases with increasing test force.

4.2 Grindability (ISO 12844)

The grindability according to ISO 12844 allows for a comparison to be made between the grinding processes used with different glasses. Twenty samples of the glass to be classified are ground for 30 seconds in a standardized diamond pellet tool under predetermined conditions. The removed volume of glass is then compared to that of the reference glass, N-SK16. The value for N-SK16 is arbitrarily set to 100.

Classification takes place according to the following scheme.

Table 4.1: Grindability (according to ISO 12844)

Grindability class	Grindability
HG 1	≤ 30
HG 2	$> 30 \leq 60$
HG 3	$> 60 \leq 90$
HG 4	$> 90 \leq 120$
HG 5	$> 120 \leq 150$
HG 6	> 150

The grindability of N-SK16 is defined as 100.

According to this scheme, the removal of glass volume during grinding is less in the lower classifications and higher in the upper classifications than for the reference glass N-SK16.

4.3 Viscosity

Glasses run through three viscosity ranges between the melting temperature and room temperature: the melting range, the super cooled melt range, and the solidification range. The viscosity of glass constantly increases during cooling of the melt (10^0 – 10^4 dPa·s). A transition from a liquid to a plastic state can be observed between 10^4 and 10^{13} dPa·s.

The so-called softening point EW identifies the plastic range in which glass parts rapidly deform under their own weight. This is the temperature $T_{10}^{7,6}$ at which glass exhibits a viscosity of $10^{7.6}$ dPa·s. The glass structure can be described as solidified or “frozen” above 10^{13} dPa·s. At this viscosity, the internal stress in glass equalizes in approx. 15 minutes.

Another way to identify the transformation range is to observe the change in the rate of relative linear thermal expansion. In accordance with ISO 7884-8, this can be used to determine the so-called transformation temperature T_g . It generally lies close to T_{10}^{13} .

Precision optical surfaces may deform and refractive indices may change if a temperature of $T_{10}^{13} - 200\text{K}$ is exceeded during any type of thermal treatment.

4.4 Coefficient of Linear Thermal Expansion

The typical curve of linear thermal expansion of glass starts near absolute zero with an increase in slope to approximately room temperature. Then, a nearly linear increase to the beginning of the noticeable plastic behavior follows. The transformation range is characterized by a distinct bending of the expansion curve that results from the increasing structural movement in the glass. Above this range, expansion again shows a nearly linear increase, but with a noticeably greater rate of increase.

Due to the dependence of the coefficient of linear thermal expansion α on temperature, two average linear thermal expansion coefficients α are usually shown for the following temperature ranges:

α (-30°C ; $+70^{\circ}\text{C}$) as the relevant information for characterizing glass behavior at room temperature (listed in the data section).

α ($+20^{\circ}\text{C}$; $+300^{\circ}\text{C}$) as the standard international value for comparison purposes for orientation during the melting process and for temperature change loading.

5 Thermal Properties

5.1 Thermal Conductivity

The range of values for thermal conductivity for glasses at room temperature extends from 1.38 W/(m·K) (pure quartz glass) to about 0.5 W/(m·K) (glasses with high lead concentrations). The most commonly used silicate glasses have values between 0.9 and 1.2 W/(m·K).

The thermal conductivities shown in the data sheets apply for a glass temperature of 90°C.

5.2 Heat Capacity

The mean isobaric specific heat capacity c_p (20°C; 100°C) is listed for some glasses as measured from the heat transfer of a hot glass at 100°C in a liquid calorimeter at 20°C. The range of values for c_p (20°C; 100°C) and the true heat capacity c_p (20°C) for silicate glasses lies between 0.42 and 0.84 J/(g·K).

6 Delivery Quality

6.1 Quality Management and Quality Assurance

Advanced Optics Business Segment of SCHOTT AG in Mainz operates a global Quality Management System on the basis of ISO9001/ISO14001. The certification is performed by Lloyd's Register Quality Assurance, Cologne/Germany.

The research laboratories of Advanced Optics in Mainz for the measurement of physical and chemical properties are accredited by the German authority GAZ Association for the Accreditation and Certification GmbH on the basis of the standard series ISO 17025:2005-08. Regular round robin tests are performed with the PTB, "Physikalisch-Technische Bundesanstalt" in Braunschweig, Germany. The PTB is a national metrology institute

that provides scientific and technical services (<http://www.ptb.de/index.en.html>), an institution similar to the NIST in the United States.

Optical glass as a technical material requires well-defined reproducible properties that a designer can rely on. Quality assurance of these properties is based on sample-based statistical measurement, partly 100 % measurement, of the optical and internal quality properties during continuous production of optical glass and on customer-specific individual measurement of cut blanks.

Professional work with high-quality materials requires precise knowledge of their properties. Hence, as Fraunhofer has already realized, progress in the production of optical glasses and their applications is always limited by the measurement capabilities. Ever growing quality demands for industrial and research applications require constant improvement of measurement technology, which is still going on.

6.2 Standard Delivery Quality

If no special quality steps are requested, the glass will be delivered in refractive index/Abbe number step 3/3 with a standard test report. The standard test report refers to a delivery lot that fulfills the standard variation tolerance. The refractive index variation from batch to batch within a lot will not exceed $\pm 1 \cdot 10^{-4}$ ($\pm 2 \cdot 10^{-4}$ for pressings, if requested). The glass is tested for bubbles and inclusions, striae, and stress birefringence.

Production of optical glass is a stable process, with only small variations in the chemical, mechanical and thermal properties of the glass. These properties are statistically controlled datasheet reference values and not measured individually upon order.

6.3 Enhanced Delivery Quality

Additional quality steps are offered based on the following table.

Table 6.1: Additional quality steps for various forms of supply

	Glass for hot processing	Pressings	Fine annealed glass	Cut blanks
Refractive index – Abbe number steps	2, 1 3, 2, 1	2, 1 3, 2, 1	2, 1 3, 2, 1	2, 1 3, 2, 1
Test certificates	Annealing schedule	Standard (S)	Standard (S)	Standard (S)
Measurement accuracy, measurement ranges	With data on the annealing rates for the achievable refractive index – Abbe number steps after fine annealing	If variation tolerance is requested	Standard with enhanced accuracy (SE)	Standard with enhanced accuracy (SE), precision (PZ), dn/dT (DNDDT)
Refractive index scattering	S0, S1	LH1, LH2	S0, S1	S0, S1
Homogeneity	–	–	–	H1–H5
Stress birefringence	–	SK	SK	SK, SSK
Striae	–	VS1	–	VS1, VS2
Bubbles/inclusions	–	VB, EVB	–	VB, EVB
Remarks			One surface can be worked	Striae and homogeneity measured in the same direction

The quality steps listed within a form of supply can be combined with one another. However, melts that are suited for various combinations are not always available.

We recommend checking availability with us as early as possible.

Requirements that exceed the quality steps mentioned can also be met. Please ask for further details.

7 Forms of Supply and Tolerances

Advanced Optics masters the entire value chain: from customer-specific glass development and its production all the way to high-precision optical product finishing, processing and measurement. By leveraging our extensive capabilities in the area of processing (polishing, coating, bonding, etc.), we offer a wide variety of custom-made optical components such as lenses (aspherical, spherical, cylindrical), prisms, mirrors, wafers, substrates and more.

Here, you will find a selection of available supply forms:

7.1 Raw Glass

7.1.1 Blocks

Blocks have up to five unworked, as-cast surfaces. Usually, at least one surface has been worked. The edges are rounded. Blocks are fine annealed and thus suited for cold working.

Described by: *Length, width, thickness*

7.1.2 Strips

Strips normally have unworked or ground surfaces and broken or cut ends. Strips are either coarse annealed or fine annealed. Coarse annealed strips are only suited for reheat pressings.

Described by: *Length, width, thickness*

7.2 Cut Blanks

7.2.1 Plates

Plates are quadrilateral fabricated parts. All six sides are worked; the edges have protective bevels.

Described by: *Length, width, thickness*

We achieve surface roughnesses of $R_a = 20\text{--}25\ \mu\text{m}$ with standard processing. Plates with closer dimensional tolerances and finer surfaces are possible upon request.

Table 7.1: Dimensional tolerances and minimum dimensions for plates

Maximum edge length [mm]	Admissible tolerances				Minimum thickness ¹⁾ [mm]
	For edge length		For thickness		
	Standard [mm]	Precision [mm]	Standard [mm]	Precision [mm]	
> 3–80	± 0.2	± 0.1	± 0.3	± 0.15	2
> 80–120	± 0.3	± 0.15	± 0.5	± 0.25	4
> 120–250	± 0.5	± 0.25	± 0.5	± 0.25	6
> 250–315	± 0.9	± 0.45	± 0.8	± 0.4	8
> 315–400	± 1.2	± 0.6	± 0.8	± 0.4	8
> 400–500	± 1.3	± 0.65	± 0.8	± 0.4	20
> 500–630	± 1.5	± 0.75	± 0.8	± 0.4	20
> 630–800	± 1.8	± 0.9	± 0.8	± 0.4	20

> 1000	Inquire	Inquire	Inquire	Inquire	

¹⁾ Lower thicknesses than listed are possible. Please ask for details.

7.2.2 Round plates

Round plates are cylindrical parts for which the diameter is larger than the thickness. Round plates are machined on all surfaces.

Described by: *Diameter, thickness*

We achieve surface roughness of $R_a = 20\text{--}25\ \mu\text{m}$ with standard processing. Round plates with closer dimensional tolerances and finer surfaces are possible upon request.

Table 7.2: Dimensional tolerances and minimum dimensions for round plates

Diameter [mm]	Admissible tolerances				Minimum thickness ¹⁾ [mm]
	For diameter		For thickness		
	Standard [mm]	Precision [mm]	Standard [mm]	Precision [mm]	
> 3–80	± 0.2	± 0.1	± 0.3	± 0.15	2
> 80–120	± 0.3	± 0.15	± 0.5	± 0.25	4
> 120–250	± 0.3	± 0.15	± 0.5	± 0.25	6
> 250–500	± 0.5	± 0.25	± 0.8	± 0.4	20
> 500–800	± 0.8	± 0.4	± 0.8	± 0.4	20
> 800–1250	± 1.0	± 0.5	± 0.8	± 0.4	40
> 1250	Inquire	Inquire	Inquire	Inquire	

¹⁾ Lower thicknesses than listed are possible. Please ask for more details.

7.2.3 Worked rods

Worked rods are cylindrical parts that are machined on all sides. The length of a rod is always greater than its diameter.

Described by: *Diameter, length*

Table 7.3: Dimensions and tolerances for worked rods in the 6–80 mm diameter range

Diameter [mm]	Standard tolerance [mm]	Tolerances, drilled and rounded per ISO 286				Length range [mm]	Tolerance for length [%]
		[mm]	[mm]	[mm]	[mm]		
6–10	± 0.2	h11 +0/–0.09	h10 +0/–0.058	h9 +0/–0.036	h8 +0/–0.022	max. 130	± 2

> 18–30	± 0.2	h11 +0/–0.13	h10 +0/–0.084	h9 +0/–0.052	h8 +0/–0.033	max. 130	± 2
> 30–50	± 0.2	h11 +0/–0.16	h10 +0/–0.100	h9 +0/–0.062	h8 +0/–0.039	max. 130	± 2
> 50–80	± 0.3	h11 +0/–0.19	h10 +0/–0.120	h9 +0/–0.074		max. 130	± 2

7.2.4 Cut prisms

Cut prisms are prisms produced by cutting and can be ground on all sides. Equilateral and non-equilateral prisms can be produced in various forms (ridge, penta, triple prisms ...) using different fabrication technologies. Described by: *Drawing*

Table 7.4: Dimensions and tolerances for cut prisms

Maximum edge length [mm]	Tolerances for dimensions [mm]	Tolerances for width [mm]
< 50	+1.0/-0	± 0.5
50-100	+1.5/-0	± 1.0
> 100	+2.0/-0	± 1.0

7.3 Pressings

7.3.1 Pressed blanks

Pressed blanks are hot formed parts with mainly round cross sections, defined radii and bevels.

Described by:
*Diameter, center
 thickness, radius 1,
 radius 2, bevels*

Table 7.5: Dimensions and tolerances for pressed blanks (according to DIN 58 926, Part 2)

Diameter [mm]	Tolerances for diameter [mm]	Tolerances for thickness [mm]	Minimum center thickness [mm]	Minimum edge thickness [mm]	Maximum edge thickness [mm]
5–18	± 0.075	± 0.3	2	1	$0.6 \cdot \emptyset$
> 18–30	± 0.11	± 0.3	3	1.5	$0.45 \cdot \emptyset$

7.4 Optical Glass Rods for Miniaturized Ball Lenses, Discs & More!

SCHOTT offers the widest range of rods with different geometries, formats and materials.

Optical glass rods from SCHOTT for applications that use small optical components such as ball lenses, rod lenses, aspheres and discs are manufactured with the help of different unique processes.

Table 7.7: Optical Glass Rods – Specifications*

Description	Fire polished surface		Matt surface	
	Standard Quality	Premium Quality	Standard Quality	Premium Quality

8 Optical Glasses for Precision Molding

Precision molding technology for direct pressing of aspherical lenses or freeform surfaces in general has become more and more important in recent years all over the world. During the precision molding process, a glass preform with exceptionally high surface quality is shaped into its final aspherical geometry, while conserving the surface quality of the preform. The molding process is a low temperature molding process with temperatures that typically range between 500°C and 700°C. Low temperature processes help to extend the operating lifetime of the mold material.

P-glasses are newly developed low transformation temperature glasses especially for use in precision molding. The letter "P" indicates that these glasses are produced exclusively for precision molding and are lead and arsenic free. In addition, several traditional optical glasses have been identified to be suited for precision molding mainly because of their low glass transition temperatures.

Glasses for precision molding in general are coarse annealed glasses. They are produced in refractive index/Abbe number step 3/3 based on

2 K/h reference annealing rate. The actual refractive index of the glass within the delivery lot will differ from this value, however.

The rapid cooling rate of a precision molding process leads to an index drop that lowers the refractive index of the glass significantly compared to the initial value. The index drop is defined as the difference between the refractive index of the glass after molding and the initial refractive index based on a 2 K/h reference annealing rate.

The data section contains the n_d and Abbe number values after molding using a SCHOTT reference process. Some of these values are preliminary data based on a theoretical reference annealing rate of 5000 K/h. The catalog n_d serves as an initial refractive index based on a reference annealing rate of 2 K/h to calculate the index drop.

Furthermore, the index drop can be calculated based on a higher initial reference annealing rate of 25 K/h. For this purpose, the n_d reference value based on an annealing rate of 25 K/h is listed.

The index drop for a given glass type depends on the specific process and geometry of the part and will differ slightly from the values displayed in the data section.

In case the refractive index after molding does not meet specific customer requirements, specific index adjustments to the given process conditions are possible upon request.

The optical glasses available that are suited for use in precision molding are displayed in the data section of this catalog, which contains the newly developed P-glasses but also the traditional glasses that are suited for precision molding. The data section on low Tg glasses also contains additional information. Acid resistance according to JOGIS (Japanese Optical Glass Industrial Standard), grindability (abrasion) according to JOGIS and the yield point/sag temperature of the glass.

9 Product Range of Optical Materials

9.1 Preferred Materials

The materials listed in the first part of the data section are preferred materials. They are produced before any specific customer orders have been received and are usually kept in stock for immediate delivery. We guarantee reliable long-term supply of these materials. Preferred materials are thus recommended for use of designs in new optical systems and listed in our so-called positive list of optical glasses. The current version of the positive list of optical glasses can be found on our website.

9.2 Inquiry Glasses

The second part of the data section is comprised of inquiry glasses that are produced on a regular basis in response to specific requests. With some of these glasses, we might have stock available from previous long running projects. However, stock is not generated on purpose without receiving orders from our customers. But even if they are not available on stock, glasses will be manufactured and delivered upon request.

10 Collection of Formulas and Wavelength Table

Relative partial dispersion $P_{x, y}$ for the wavelengths x and y based on the blue F and red C hydrogen line

$$P_{x, y} = (n_x - n_y) / (n_F - n_C) \quad (10.1)$$

or based on the blue F' and red C' cadmium line

$$P'_{x, y} = (n_x - n_y) / (n_{F'} - n_{C'}) \quad (10.2)$$

Linear relationship between the Abbe number and the relative partial dispersion for "normal glasses"

$$P_{x, y} \approx a_{xy} + b_{xy} \cdot v_d \quad (10.3)$$

Deviation ΔP from the "normal lines"

$$P_{x, y} = a_{xy} + b_{xy} \cdot v_d + \Delta P_{x, y} \quad (10.4)$$

$$\Delta P_{C, t} = (n_C - n_t) / (n_F - n_C) - (0.5450 + 0.004743 \cdot v_d) \quad (10.5)$$

$$\Delta P_{C, s} = (n_C - n_s) / (n_F - n_C) - (0.4029 + 0.002331 \cdot v_d) \quad (10.6)$$

$$\Delta P_{F, e} = (n_F - n_e) / (n_F - n_C) - (0.4884 - 0.000526 \cdot v_d) \quad (10.7)$$

$$\Delta P_{g, F} = (n_g - n_F) / (n_F - n_C) - (0.6438 - 0.001682 \cdot v_d) \quad (10.8)$$

$$\Delta P_{i, g} = (n_i - n_g) / (n_F - n_C) - (1.7241 - 0.008382 \cdot v_d) \quad (10.9)$$

The position of the normal lines was determined based on value pairs of the glass types K7 and F2.

Sellmeier dispersion formula

$$n^2(\lambda) - 1 = B_1 \lambda^2 / (\lambda^2 - C_1) + B_2 \lambda^2 / (\lambda^2 - C_2) + B_3 \lambda^2 / (\lambda^2 - C_3) \quad (10.10)$$

When calculating the refractive index using the Sellmeier coefficients from the SCHOTT data sheets, the wavelength λ needs to be entered in units of μm .

Change in refractive index and Abbe number during annealing at different annealing rates

$$n_d(h_x) = n_d(h_0) + m_{nd} \cdot \log(h_x/h_0) \quad (10.11)$$

$$v_d(h_x) = v_d(h_0) + m_{vd} \cdot \log(h_x/h_0) \quad (10.12)$$

$$m_{vd} = (m_{nd} - v_d[h_0] \cdot m_{nF-nC}) / ((n_F - n_C) + 2 \cdot m_{nF-nC} \cdot \log(h_x/h_0)) \quad (10.13)$$

h_0 Beginning annealing rate

h_x New annealing rate

m_{nd} Annealing coefficient for the refractive index, depending on glass type

m_{vd} Annealing coefficient for the Abbe number, depending on glass type

m_{nF-nC} Annealing coefficient for the principal dispersion, depending on glass type

Measurement accuracy of the Abbe number

$$\sigma_{vd} \approx \sigma_{n_F - n_C} \cdot v_d / (n_F - n_C) \quad (10.14)$$

Spectral internal transmittance

$$\tau_{i\lambda} = \Phi_{e\lambda} / \Phi_{i\lambda} \quad (10.15)$$

Spectral transmittance

$$\tau_{\lambda} = \tau_{i\lambda} \cdot P_{\lambda} \quad (10.16)$$

P_{λ} factor of reflection

Fresnel reflectivity for a light beam with normal incidence, irrespective of polarization

$$R = ((n-1)/(n+1))^2 \quad (10.17)$$

Reflection factor that considers multiple reflections

$$P = (1-R)^2 / (1-R^2) = 2n / (n^2 + 1) \quad (10.18)$$

n Refractive index for the wavelength λ

Converting of internal transmittance to another layer thickness

$$\log \tau_{i1} / \log \tau_{i2} = d_1 / d_2 \text{ or} \tag{10.19}$$

$$\tau_{i2} = \tau_{i1}^{(d2/d1)} \tag{10.20}$$

τ_{i1}, τ_{i2} Internal transmittances at the thicknesses d_1 and d_2

Stress birefringence, difference in optical path

$$\Delta s = 10 \cdot K \cdot d \cdot \sigma \text{ in nm} \tag{10.21}$$

K Stress optical constant, dependent on glass type in $10^{-6} \text{ mm}^2/\text{N}$

d Length of light path in the sample in cm

σ Mechanical stress (positive for tensile stress) in N/mm^2 (= MPa)

Homogeneity from interferometrically measured wave front deviations

$$\begin{aligned} \Delta n &= \Delta W / (2 \cdot d) \\ &= \Delta W [\lambda] \cdot 633 \cdot 10^{-6} / (2 \cdot d[\text{mm}]) \end{aligned} \quad (10.22)$$

when listing the wave front deformation in units of the wavelength and a test wavelength of 633 nm (He-Ne laser)

ΔW Wave front deformation with double beam passage (interferometric testing)

d Thickness of test piece

Note: The formulas have been chosen carefully and listed.
Nevertheless, SCHOTT cannot be held responsible for errors resulting from their use.

Table 10.1: Wavelengths for selecting frequently used spectral lines

Wavelength [nm]	Designation	Spectral line used	Element
2325.42		Infrared mercury line	Hg
1970.09		Infrared mercury line	Hg
1529.582		Infrared mercury line	Hg
1060.0		Neodymium glass laser	Nd
1013.98	t	Infrared mercury line	Hg
852.11	s	Infrared cesium line	Cs
706.5188	r	Red helium line	He
656.2725	C	Red hydrogen line	H
643.8469	C'	Red cadmium line	Cd
632.8		Helium-neon gas laser	He-Ne
589.2938	D	Yellow sodium line	Na
		(center of the double line)	

Wavelength [nm]	Designation	Spectral line used	Element
587.5618	d	Yellow helium line	He
546.0740	e	Green mercury line	Hg
486.1327	F	Blue hydrogen line	H
479.9914	F'	Blue cadmium line	Cd
435.8343	g	Blue mercury line	Hg
404.6561	h	Violet mercury line	Hg
365.0146	i	Ultraviolet mercury line	Hg
334.1478		Ultraviolet mercury line	Hg
312.5663		Ultraviolet mercury line	Hg
296.7278		Ultraviolet mercury line	Hg
280.4		Ultraviolet mercury line	Hg
248.3		Ultraviolet mercury line	Hg

Glossary

Glass Code	– International glass code of refractive index n_d and Abbe number v_d with density	HG	– Grindability class (ISO 12844)
$n_x, v_x, n_x - n_y$	– Refractive index, Abbe number, and dispersion at various wavelengths	B	– Bubble class
$P_{g,F}, \Delta P_{g,F}$	– Relative partial dispersion and deviation of relative partial dispersion from the normal line between g and F line	τ_1 (10/400)	– Internal transmittance at 400 nm; glass thickness: 10 mm
CR	– Climatic resistance class (ISO/WD 13384)	FC	– Color Code: Wavelength for transmittance 0.80 (at*: 0.70) and 0.05; glass thickness: 10 mm (JOGIS)
FR	– Stain resistance class	Only precision molding glasses:	
SR	– Acid resistance class (ISO 8424)	Abrasion Aa	– Grindability according to JOGIS
AR	– Alkali resistance class (ISO 10629)	n_d ref.	– n_d reference value (annealing rate 25 K/h)
PR	– Phosphate resistance class (ISO 9689)	n_d, v_d after molding	– As pressed at SCHOTT (preliminary data based on annealing rate of 5000 K/h)
α (–30/+70)	– Coefficient of linear thermal expansion between –30 °C and +70 °C in $10^{-6}/K$	SR-J	– Acid resistance class according to JOGIS
T_g	– Transformation temperature in °C (ISO 7884-8)	WR-J	– Water resistance class according to JOGIS
$T_{10}^{7.6}$	– Temperature of the glass at a viscosity of $10^{7.6}$ dPa s	AT	– Yield point/sag temperature in °C
ρ	– Density in g/cm^3	α (20/300)	– Coefficient of linear thermal expansion between +20 °C and +300 °C in $10^{-6}/K$
HK	– Knoop hardness (ISO 9385)	JOGIS	– Japanese Optical Glass Industrial Standards

The data listed is the most accurate data currently available.

We reserve the right to make changes due to technical progress.
